

Sales Performance Report

Day-of-Week Sales Cadence, Product, and Customer Concentration

Data window: Jan 1, 2020 – Dec 31, 2026 | Scope: paid and confirmed orders only

Executive Summary

This report analyzes 41,700 paid or confirmed orders totaling R\$1.20 billion in revenue across the observed period. Three questions are addressed: (1) does demand vary meaningfully by day of the week, (2) how concentrated is revenue across products, and (3) how concentrated is revenue across customers.

Metric	Value
Total qualifying orders	41,700
Total revenue (paid/confirmed)	R\$ 1,199,367,079.54
Ecommerce share of revenue	70.1%
Physical store (POS) share of revenue	29.9%
Orders excluded (cancelled/draft)	7,298 (14.9% of all orders)

- Day-of-week demand is nearly flat once ecommerce is included (< 4% spread between best and worst day), but physical stores alone show a clearer, still modest, weekly pattern (~10% spread).
- Product revenue is not concentrated: the top 10 of 496 products sold account for only 5.4% of total revenue.
- Customer revenue is even less concentrated: the top 10 of 2,000 customers account for under 1% of total revenue, with no single customer exceeding 0.1% — this book of business is broad-based, not dependent on a handful of accounts.
- A likely test/placeholder product named “asdf” ranks #1 by revenue (R\$8.3M, 0.7% of total) — recommend validating with the source system before this feeds any downstream decision.

Methodology & Data Notes

Status filter

All figures include only orders with status paid or confirmed. Cancelled and draft orders (7,298 rows, 14.9% of the raw order table) are excluded throughout, since they don't represent collected or committed revenue.

Day-of-week averages

Averages are computed per calendar weekday across the full date range (Jan 1, 2020 – Dec 31, 2026: 365–366 occurrences of each weekday), not per weekday-with-at-least-one-sale. Concretely: $\text{average} = (\text{sum of revenue or order count on that weekday}) \div (\text{number of calendar dates that fell on that weekday in the range})$. This ensures any zero-sale day would pull the average down rather than being silently dropped from the denominator.

Channel split

“Physical stores only” restricts orders to `channel = 'pos'`. “Ecommerce included” uses all channels (`pos + ecommerce`). Ecommerce is the larger channel by both revenue and order count (70% vs. 30%).

Revenue and concentration figures

Product revenue is the sum of `line_total` across `order_items`, joined to orders (status-filtered), `product_variants`, and products. Customer revenue is the sum of order total per `customer_id`, joined to customers table for `legal_name`. “Losses per product” were evaluated but not included: no line item or order in this dataset sells below cost, even after discounts, so a cost-basis loss metric returns zero everywhere and isn't a meaningful cut of this data.

Sales Cadence by Day of Week

The pattern differs meaningfully depending on whether ecommerce is included. Physical stores show a real, if modest, weekly rhythm; blending in ecommerce mostly washes it out.

Physical stores only

Figure 1–2. Average revenue and order volume per calendar day of week, POS channel only.

Key stats — Physical stores

Revenue peaks Wednesday (R\$147,949/day) and troughs Thursday (R\$134,118/day) — a 9.9% spread relative to the mean (coefficient of variation 3.8%). Order volume peaks Tuesday (5.0/day) and troughs Sunday (4.7/day), a 6.5% spread. Weekday average revenue (R\$141,471) runs about 2.8% above the weekend average (R\$137,607).

Ecommerce included (all channels)

Figure 3–4. Average revenue and order volume per calendar day of week, all channels.

Key stats — All channels

With ecommerce blended in, the weekly pattern compresses sharply: revenue spread falls to 3.8% (CV 1.4%) and volume spread to 4.7% (CV 1.5%). Tuesday remains the strongest day for both revenue and volume; Thursday is weakest for revenue, Sunday weakest for volume. Weekday vs. weekend revenue is nearly identical (R\$470,363 vs. R\$465,775, ~1% apart).

Product Performance

Figure 5. Top 10 products by accumulated gross revenue (paid/confirmed orders only).

Key stats — Products

496 distinct products generated revenue in the period. The top 10 account for just 5.4% of total product revenue (R\$1.23B). The top-ranked entry, “asdf” (R\$8.3M, 0.68% of revenue), does not match the naming convention of any other product and should be verified as a genuine product rather than test data before being used in merchandising decisions.

Because concentration is low, product-level revenue growth is more likely to come from broad catalog performance than from doubling down on a handful of hero products — worth confirming against margin data (not available in this dataset) before drawing merchandising conclusions, since high-revenue products are not necessarily the most profitable ones.

Customer Concentration

Figure 6. Top 10 customers by accumulated gross revenue, by legal name (paid/confirmed orders only).

Key stats — Customers

2,000 distinct customers purchased in the period. The top 10 account for under 1% of total revenue (0.91%), and the single largest customer (Freitas Ltda, R\$1.21M) represents only 0.10% of total revenue. This is a low-concentration, broad-based customer base — there is a caveat on margin: revenue rank is not the same as profitability rank.

Appendix: Assumptions & Caveats

- Revenue figures are gross order/line totals (post line-level discount, as recorded in `total` / `line\_total`), not profit or contribution margin.
- Date range reflects the span of `placed\_at` values present in the uploaded orders table (2020-01-01 to 2026-12-31); it was not independently verified against a business “go-live” date.
- “Losses per product” (cost-basis) returns zero across the entire dataset and was excluded from this report — flagged here in case that’s itself a data-generation artifact worth checking with the source system.
- The “asdf” product entry is presented as-is; it has not been excluded from any totals in this report so that all totals remain reconcilable to the underlying tables.
